# Part 2: Inside the Machine

Why do you care?

The internal  
components

influence

the capabilities of the  
machine

AND

its expandability.

Is this  
good for  
running fsl?

How many  
images will it  
hold?

Can I add  
more memory?

Is it fast and  
reliable?

# Welcome to the Machine

# The Case influences

- motherboard type
- # of components
- Cooling
- and Noisiness

# Case with Components

# Power Supply

Too small (too few watts) is a problem, too big is not.

**Warning:** Video cards are power pigs.

You also want to make  
sure that your hard  
drive is big enough for  
your data (twice as big  
is good)

# Storage: Hard Drives (HDDs)

# The Motherboard (Main Board)

# Motherboard: Old

# Motherboard: New

The motherboard  
limits choices for all  
other components:

cards

ram

cpu

**cards**

PCI DIGITAL AUDIO BOARD  
**SE-200PCI LTD**

Cards plug in to  
motherboard slots.

Card edge connectors

must match slots

(i.e., PCI-E cards won't  
fit or work in PCI  
slots)

So, the slots provided on your motherboard limit the types of cards you can use.

Cards provide ports  
for your peripherals.

Why are there  
different kinds of  
slots?

Part of the reason is  
historical.

1981

The ISA card  
(Industry Standard  
Architecture)

8 bit, then 16 bit

4.7 MHz

1992

The PCI card  
(Peripheral Component  
Interconnect)

32 bit, 33 MHz

1997

The AGP card  
(Accelerated Graphics  
Port)

32 bit, 66-533 MHz

~2000

The PCI-X card  
(Peripheral Component  
Interconnect  
eXtended)

64 bit, 133-533 MHz

2004

The PCI-E card

(Peripheral Component  
Interconnect-Express)

64 bit, up to 4000  
MHz

Video cards have  
driven much of this  
need for speed

# Video Cards

Modern videocards are  
like separate little  
computers.

They have their own  
Graphical Processing  
Unit and RAM.

Big LCD monitors  
(helpful for imaging  
work) are 1920x1200  
or even 2048x1536.

Not all videocards  
handle those  
resolutions.

GPU, videocard ram  
and video ports (vga,  
dvi, hdmi) all matter

However, you do not need top-of-the-line videocards for most imaging work.

Why?

Because top-of-the-line videocards are built to render fast moving hi-resolution images in games.

So far, even when we  
do 3D stuff, it is  
usually just one  
rendering that might  
be rotated....

We want high  
resolution monitors,  
(maybe 2), and some  
fairly simple  
rendering.

512 MB of Video RAM  
and 2 DVI or HDMI  
ports will probably do  
the job.

Ethernet and sound  
are often built in, so  
you may not need any  
other cards.

You may want to make sure you have gigabit ethernet...so you can move big files across the network quickly.

# Gigabit Ethernet card

RAM

More RAM (Random Access Memory) can manipulate more data at one time.

Faster RAM, can move data through more quickly.

Both speed and amount of RAM are important for imaging.

# RAM

Motherboard slots hold one kind of ram (e.g, DDR2), and not the other...so the motherboard you have limits the amount and type (speed) of the RAM you can use.

Watch Out! Companies often  
save money by putting few  
RAM slots on motherboards,  
this really limits expansion!  
Videocards have their own  
ram, usually much faster than  
system RAM

cpu

# Processing

Number and speed of CPUs  
(central processing units)  
roughly determines processing  
capability of the machine (e.g.,  
how fast it can do the  
mathematical operations)

# CPU

# Summary

- Purchase for the motherboard and cpu
  - And for RAM expandability.
- Understand what parts are compatible with your motherboard, and each other.
